Maximal oxygen consumption (VO$_2$max) tests typically end at the point of volitional exhaustion. Yet, prior research with averagely fit individuals and highly fit NCAA female athletes suggest that concluding a maximal treadmill test with 2min active recovery and allowing subjects to exercise a second time (ie. a booster test) at the workload eliciting the initial volitional exhaustion results in significantly greater VO$_2$max values (1.4% and 4.2% mean increase, respectively). The potential effects of this testing sequence (ie. 2min active recovery) on VO$_2$max treadmill graded exercise tests (GXT) has not been evaluated utilizing ultramarathon runners, yet accurate assessment of these unique athletes’ VO$_2$max is crucial. PURPOSE: To examine changes in VO$_2$max values, in fit ultramarathon runners, following 2min of active recovery at the conclusion of a treadmill GXT to volitional exhaustion. METHODS: Twenty-nine (m = 19, f = 10) ultramarathon runners completed a max treadmill GXT by reaching volitional exhaustion (MX1). Immediately following 2min active recovery (at 0% grade & 2.5 mph), subjects exercised to volitional exhaustion a second time (MX2). MX1 and MX2 were compared using a Paired-Samples t-Test with significant differences occurring at $p \leq 0.05$. RESULTS: MX1 (53.9 ± 6.0 ml/kg/min) was significantly different ($p = 0.03$) than MX2 (52.7 ± 7.0 ml/kg/min). The mean change from MX1 to MX2 was -2.2%, yet 37.9% of the subjects benefited (+2.9% mean increase) from the booster test with individual increases of +0.2% up to +8.0%. CONCLUSION: Mean results suggest that 2min active recovery may not allow significantly greater VO$_2$max values to be achieved by fit ultramarathon runners during a max treadmill GXT, yet 37.9% of the subjects increased their VO$_2$max during the “booster max” treadmill protocol. Future research may examine if fitness level, training experience, age, ultramarathon distance specialty, or other variables might affect this exercise testing protocol.
